Lecture 7: 26 November 2020

Today

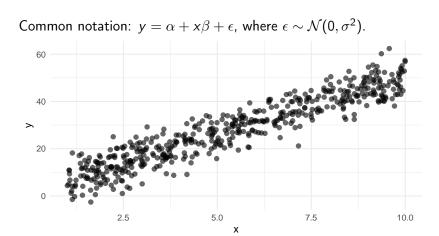

Today

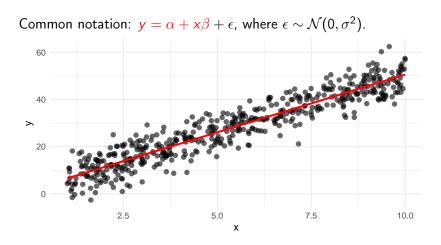

► Statistical models (continued).

Today

- Statistical models (continued).
- ▶ Introduction to causal inference.

Common notation: $y = \alpha + x\beta + \epsilon$, where $\epsilon \sim \mathcal{N}(0, \sigma^2)$.

```
# Specify regression line
model < -lm(y ~ x, data)
model
##
## Call:
## lm(formula = y ~ x, data = data)
##
## Coefficients:
## (Intercept)
                         X
##
        1.647 4.888
```

```
# Extract residuals
Residuals <- model$residuals</pre>
```

```
# Extract residuals

$$Y \sim \mathcal{N}(y \mid \mu, \sigma^2) \tag{1}$$

$$\mu = x\beta \tag{2}$$

$$Y \sim \mathcal{N}(y \mid \mu, \sigma^2) \tag{1}$$

$$\mu = \mathsf{x}\beta\tag{2}$$

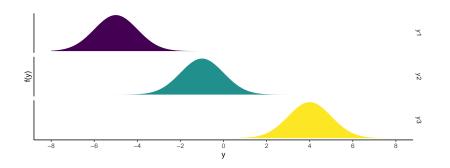

Alternative notation:

$$Y \sim \mathcal{N}(y \mid \mu, \sigma^2) \tag{1}$$

$$\mu = x\beta \tag{2}$$

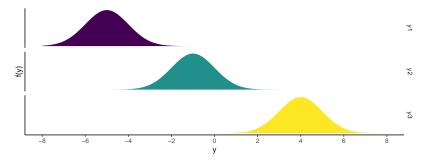

▶ (1) is the stochastic component of the model.

$$Y \sim \mathcal{N}(y \mid \mu, \sigma^2)$$
 (1)

$$\mu = x\beta \tag{2}$$

- ▶ (1) is the stochastic component of the model.
- ▶ (2) is the systematic component of the model.

$$\mathbb{E}(Y \mid X = x).$$

▶ To understand the association between *Y* and *X*, we are interested in a *conditional expectation*:

$$\mathbb{E}(Y \mid X = x).$$

▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.

$$\mathbb{E}(Y \mid X = x).$$

- ▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.
- ▶ The collection of all possible population averages of *Y* is known as the *conditional expectation function* (CEF).

$$\mathbb{E}(Y \mid X = x).$$

- ▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.
- ▶ The collection of all possible population averages of *Y* is known as the *conditional expectation function* (CEF).
- ▶ $\mathbb{E}(Y \mid X)$ is the CEF function.

$$\mathbb{E}(Y \mid X = x).$$

- ▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.
- ▶ The collection of all possible population averages of *Y* is known as the *conditional expectation function* (CEF).
- ▶ $\mathbb{E}(Y \mid X)$ is the CEF function.
- ▶ $\mathbb{E}(Y \mid X = x)$ is a specific value of the CEF function.

$$\mathbb{E}(Y \mid X = x).$$

- ▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.
- ▶ The collection of all possible population averages of *Y* is known as the *conditional expectation function* (CEF).
- ▶ $\mathbb{E}(Y \mid X)$ is the CEF function.
- ▶ $\mathbb{E}(Y \mid X = x)$ is a specific value of the CEF function.
- ▶ The CEF is exactly linear if it is a linear function of X:

$$\mathbb{E}(Y \mid X) = \alpha + x\beta.$$

▶ To understand the association between *Y* and *X*, we are interested in a *conditional expectation*:

$$\mathbb{E}(Y \mid X = x).$$

- ▶ A conditional expectation tells us how the population average of *Y* changes as we change the conditioning variable *X*.
- ▶ The collection of all possible population averages of *Y* is known as the *conditional expectation function* (CEF).
- ▶ $\mathbb{E}(Y \mid X)$ is the CEF function.
- $ightharpoonup \mathbb{E}(Y \mid X = x)$ is a specific value of the CEF function.
- ▶ The CEF is exactly linear if it is a linear function of X:

$$\mathbb{E}(Y \mid X) = \alpha + x\beta.$$

▶ If the CEF is not exactly linear, then the regression of Y on X gives the best linear approximation to this non-linear CEF (this is done by minimising the squared deviation between the values of the linear model and those of the CEF).

Recall that $\mathbb{V}(X)$ is measure of variation in X and Cov(Y,X) is a measure of the tendency of Y and X to go up or down together.

Recall that $\mathbb{V}(X)$ is measure of variation in X and Cov(Y,X) is a measure of the tendency of Y and X to go up or down together.

Theorem

If
$$\mathbb{E}(Y \mid X) = \alpha + x\beta$$
, then

$$\beta = \frac{\mathsf{Cov}(Y,X)}{\mathbb{V}(X)}.$$

Recall that $\mathbb{V}(X)$ is measure of variation in X and Cov(Y,X) is a measure of the tendency of Y and X to go up or down together.

Theorem

If $\mathbb{E}(Y \mid X) = \alpha + x\beta$, then

$$\beta = \frac{\mathsf{Cov}(Y,X)}{\mathbb{V}(X)}.$$

▶ In words: β quantifies the portion of variation in X that is also associated with variation in Y.

Recall that $\mathbb{V}(X)$ is measure of variation in X and Cov(Y,X) is a measure of the tendency of Y and X to go up or down together.

Theorem

If $\mathbb{E}(Y \mid X) = \alpha + x\beta$, then

$$\beta = \frac{\mathsf{Cov}(Y,X)}{\mathbb{V}(X)}.$$

- In words: β quantifies the portion of variation in X that is also associated with variation in Y.
- ▶ If Y and X are uncorrelated, then $\beta = 0$.

Recall that $\mathbb{V}(X)$ is measure of variation in X and Cov(Y,X) is a measure of the tendency of Y and X to go up or down together.

Theorem

If $\mathbb{E}(Y \mid X) = \alpha + x\beta$, then

$$\beta = \frac{\mathsf{Cov}(Y,X)}{\mathbb{V}(X)}.$$

- In words: β quantifies the portion of variation in X that is also associated with variation in Y.
- ▶ If Y and X are uncorrelated, then $\beta = 0$.
- ▶ But if $\beta \neq 0$, does that mean X causes Y?

Correlation between age of Miss America and murders by steam, hot vapours, and hot objects:

Correlation between age of Miss America and murders by steam, hot vapours, and hot objects: 0.87.

- Correlation between age of Miss America and murders by steam, hot vapours, and hot objects: 0.87.
- Correlation between consumption of mozzarella cheese and civil engineering doctorates awarded:

- ▶ How do we know if an association is causal?

▶ Patient A receives a heart transplant. Five days later, he dies.

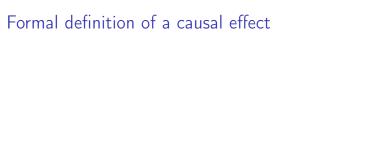

- ▶ Patient A receives a heart transplant. Five days later, he dies.
- ▶ Patient *B* receives a heart transplant. Five days later, she is alive.

- ▶ Patient *A* receives a heart transplant. Five days later, he dies.
- ▶ Patient *B* receives a heart transplant. Five days later, she is alive.
- ► Counterfactual: what would have happened if *A* and *B* had not received heart transplants?

- ▶ Patient *A* receives a heart transplant. Five days later, he dies.
- ▶ Patient *B* receives a heart transplant. Five days later, she is alive.
- Counterfactual: what would have happened if A and B had not received heart transplants?
- Causal inference involves the comparison of outcomes between scenarios where an action is taken versus when the action is withheld.

- ▶ Patient *A* receives a heart transplant. Five days later, he dies.
- ▶ Patient *B* receives a heart transplant. Five days later, she is alive.
- Counterfactual: what would have happened if A and B had not received heart transplants?
- Causal inference involves the comparison of outcomes between scenarios where an action is taken versus when the action is withheld.
- If the two outcomes differ, we say that the action had a causal effect (positive or negative) on the outcome. Otherwise, the action has no causal effect.

- ▶ Patient *A* receives a heart transplant. Five days later, he dies.
- ▶ Patient *B* receives a heart transplant. Five days later, she is alive.
- Counterfactual: what would have happened if A and B had not received heart transplants?
- Causal inference involves the comparison of outcomes between scenarios where an action is taken versus when the action is withheld.
- If the two outcomes differ, we say that the action had a causal effect (positive or negative) on the outcome. Otherwise, the action has no causal effect.
- ► The action is referred to as an *intervention*, an *exposure*, or a *treatment*.

► Consider a binary treatment variable *T* (treated versus untreated) and an outcome variable *Y*.

- Consider a binary treatment variable T (treated versus untreated) and an outcome variable Y.
- ▶ Every individual has two *potential* or *counterfactual outcomes*: Y_1 and Y_0 .

- Consider a binary treatment variable T (treated versus untreated) and an outcome variable Y.
- ▶ Every individual has two *potential* or *counterfactual outcomes*: Y_1 and Y_0 .
- ▶ Y_1 is the outcome under treatment: the value of outcome variable when the individual has treatment value T = 1.

- Consider a binary treatment variable T (treated versus untreated) and an outcome variable Y.
- ▶ Every individual has two *potential* or *counterfactual outcomes*: Y_1 and Y_0 .
- ▶ Y_1 is the outcome under treatment: the value of outcome variable when the individual has treatment value T = 1.
- Y₀ is the outcome under non-treatment (or *control*): the value of outcome variable when the individual has treatment value T=0.

- Consider a binary treatment variable T (treated versus untreated) and an outcome variable Y.
- ▶ Every individual has two *potential* or *counterfactual outcomes*: Y_1 and Y_0 .
- ▶ Y_1 is the outcome under treatment: the value of outcome variable when the individual has treatment value T = 1.
- ▶ Y_0 is the outcome under non-treatment (or *control*): the value of outcome variable when the individual has treatment value T = 0.
- ▶ The treatment T has a causal effect on an individual's outcome Y if $Y_1 \neq Y_0$ for that individual.

- Consider a binary treatment variable T (treated versus untreated) and an outcome variable Y.
- ▶ Every individual has two *potential* or *counterfactual outcomes*: Y_1 and Y_0 .
- ▶ Y_1 is the outcome under treatment: the value of outcome variable when the individual has treatment value T = 1.
- ▶ Y_0 is the outcome under non-treatment (or *control*): the value of outcome variable when the individual has treatment value T = 0.
- ▶ The treatment T has a causal effect on an individual's outcome Y if $Y_1 \neq Y_0$ for that individual.
- ▶ The causal effect itself is defined as $Y_1 Y_0$.

Individual causal effects are defined as a contrast between values of counterfactual outcomes.

- ▶ Individual causal effects are defined as a contrast between values of counterfactual outcomes.
- ► Problem: only one counterfactual outcome is observed for each individual.

- Individual causal effects are defined as a contrast between values of counterfactual outcomes.
- Problem: only one counterfactual outcome is observed for each individual.
- ▶ Next best thing: average causal effect in the population.

- Individual causal effects are defined as a contrast between values of counterfactual outcomes.
- Problem: only one counterfactual outcome is observed for each individual.
- ▶ Next best thing: average causal effect in the population.
- An average causal effect in the population is present if

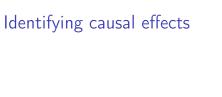

$$\mathbb{E}(Y_1) \neq \mathbb{E}(Y_0)$$
.

- Individual causal effects are defined as a contrast between values of counterfactual outcomes.
- Problem: only one counterfactual outcome is observed for each individual.
- Next best thing: average causal effect in the population.
- An average causal effect in the population is present if

$$\mathbb{E}(Y_1) \neq \mathbb{E}(Y_0).$$

► The population average treatment effect (PATE) is defined as a contrast between expected values of counterfactual outcomes:

$$\mathbb{E}(Y_1-Y_0)=\mathbb{E}(Y_1)-\mathbb{E}(Y_0).$$

▶ You are interested in the average causal effect of *T* on *Y*.

- ▶ You are interested in the average causal effect of T on Y.
- ▶ You collect information on Y for two groups: a treatment group (T = 1) and a control group (T = 0).

- ▶ You are interested in the average causal effect of *T* on *Y*.
- You collect information on Y for two groups: a treatment group (T=1) and a control group (T=0).
- ▶ You calculate $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$.

- ▶ You are interested in the average causal effect of T on Y.
- You collect information on Y for two groups: a treatment group (T=1) and a control group (T=0).
- ▶ You calculate $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$.
- ▶ Have you obtained your quantity of interest?

▶ $\mathbb{E}(Y \mid T = 1) - \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.

- ▶ $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.
- ▶ An association involves a contrast between two (disjoint) subsets of the population defined by the actual value of *T*.

- ▶ $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.
- ➤ An association involves a contrast between two (disjoint) subsets of the population defined by the actual value of T.
- ▶ Problem: the two subsets can be systematically different in ways that affect the association between *T* and *Y*.

- ▶ $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.
- ▶ An association involves a contrast between two (disjoint) subsets of the population defined by the actual value of *T*.
- ▶ Problem: the two subsets can be systematically different in ways that affect the association between *T* and *Y*.
- Causal inferences are concerned with "what if" questions in counterfactual worlds where everyone would receive treatment and control (not at the same time!).

- ▶ $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.
- ▶ An association involves a contrast between two (disjoint) subsets of the population defined by the actual value of *T*.
- ▶ Problem: the two subsets can be systematically different in ways that affect the association between *T* and *Y*.
- Causal inferences are concerned with "what if" questions in counterfactual worlds where everyone would receive treatment and control (not at the same time!).
- Hence, causation is defined by a contrast in the same population (or two otherwise identical populations) under two different values of T.

- ▶ $\mathbb{E}(Y \mid T = 1) \mathbb{E}(Y \mid T = 0)$ calculates a contrast between the portion of the population who receive treatment and the portion who receive no treatment.
- ▶ An association involves a contrast between two (disjoint) subsets of the population defined by the actual value of *T*.
- ▶ Problem: the two subsets can be systematically different in ways that affect the association between *T* and *Y*.
- Causal inferences are concerned with "what if" questions in counterfactual worlds where everyone would receive treatment and control (not at the same time!).
- ▶ Hence, *causation* is defined by a contrast in the same population (or two otherwise identical populations) under two different values of *T*.
- Key challenge: how do we ensure that the treatment and control groups are exchangeable (they have the same pre-treatment characteristics)?

▶ In a *randomised controlled trial*, each unit is randomly assigned to either the treatment or the control group.

- In a randomised controlled trial, each unit is randomly assigned to either the treatment or the control group.
- ➤ The randomisation of treatment assignment guarantees that the average difference in outcome between the treatment and control groups is caused by the treatment alone, because the two groups are otherwise identical (on average).

- In a randomised controlled trial, each unit is randomly assigned to either the treatment or the control group.
- ➤ The randomisation of treatment assignment guarantees that the average difference in outcome between the treatment and control groups is caused by the treatment alone, because the two groups are otherwise identical (on average).
- Exchangeability implies that the assigned treatment is independent of the potential outcomes:

$$\mathbb{E}(Y_T \mid T=1) = \mathbb{E}(Y_T \mid T=0).$$

- In a randomised controlled trial, each unit is randomly assigned to either the treatment or the control group.
- ➤ The randomisation of treatment assignment guarantees that the average difference in outcome between the treatment and control groups is caused by the treatment alone, because the two groups are otherwise identical (on average).
- Exchangeability implies that the assigned treatment is independent of the potential outcomes:

$$\mathbb{E}(Y_T \mid T=1) = \mathbb{E}(Y_T \mid T=0).$$

▶ This does *not* mean that the treatment is independent of the observed outcome.

- In a randomised controlled trial, each unit is randomly assigned to either the treatment or the control group.
- ➤ The randomisation of treatment assignment guarantees that the average difference in outcome between the treatment and control groups is caused by the treatment alone, because the two groups are otherwise identical (on average).
- Exchangeability implies that the assigned treatment is independent of the potential outcomes:

$$\mathbb{E}(Y_T \mid T=1) = \mathbb{E}(Y_T \mid T=0).$$

- ➤ This does not mean that the treatment is independent of the observed outcome.
- Quiz: What is the difference between an observed outcome and a potential (counterfactual) outcome?
